

Dynamic Programming | Set 7 (Coin Change)

Given a value N , if we want to make change for N cents, and we have infinite supply of each of $S = \{S_1, S_2, \dots, S_m\}$ valued coins, how many ways can we make the change? The order of coins doesn't matter.

For example, for $N = 4$ and $S = \{1, 2, 3\}$, there are four solutions: $\{1, 1, 1, 1\}, \{1, 1, 2\}, \{2, 2\}, \{1, 3\}$. So output should be 4. For $N = 10$ and $S = \{2, 5, 3, 6\}$, there are five solutions: $\{2, 2, 2, 2, 2\}, \{2, 2, 3, 3\}, \{2, 2, 6\}, \{2, 3, 5\}$ and $\{5, 5\}$. So the output should be 5.

1) Optimal Substructure

To count total number solutions, we can divide all set solutions in two sets.

- 1) Solutions that do not contain m th coin (or S_m).
- 2) Solutions that contain at least one S_m .

Let $\text{count}(S[], m, n)$ be the function to count the number of solutions, then it can be written as sum of $\text{count}(S[], m-1, n)$ and $\text{count}(S[], m, n-S_m)$.

Therefore, the problem has optimal substructure property as the problem can be solved using solutions to subproblems.

2) Overlapping Subproblems

Following is a simple recursive implementation of the Coin Change problem. The implementation simply follows the recursive structure mentioned above.

```
#include<stdio.h>
```

```
// Returns the count of ways we can sum S[0...m-1] coins  
int count( int S[], int m, int n )  
{  
    // If n is 0 then there is 1 solution (do not include  
    if (n == 0)  
        return 1;  
  
    // If n is less than 0 then no solution exists  
    if (n < 0)  
        return 0;  
  
    // If there are no coins and n is greater than 0, the
```

```

if (m <= 0 && n >= 1)
    return 0;

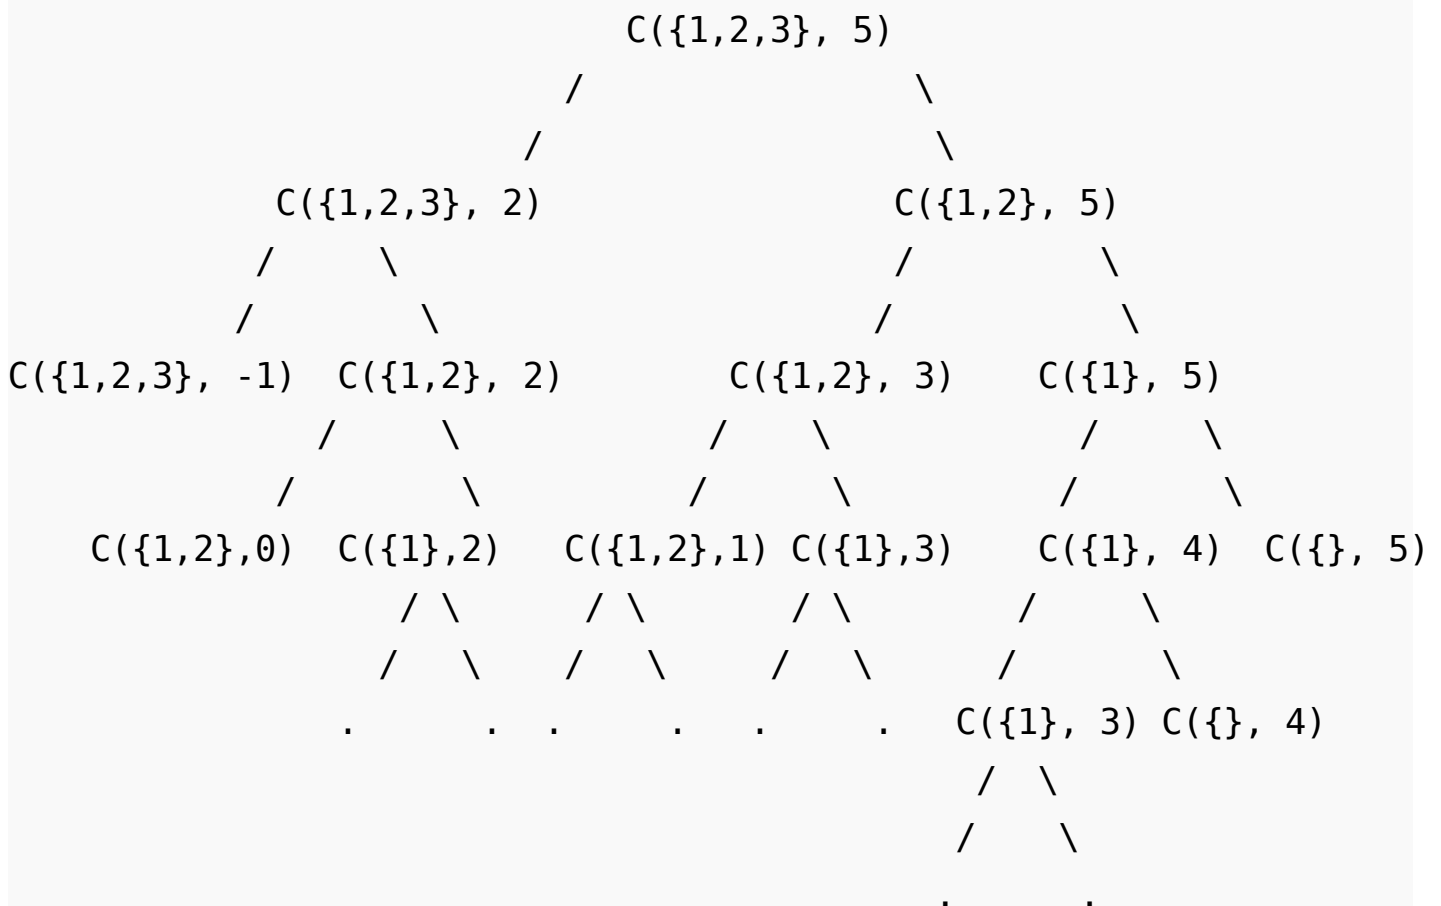

// count is sum of solutions (i) including S[m-1] (i.e. S[i])
return count( S, m - 1, n ) + count( S, m, n-S[m-1] );
}

// Driver program to test above function
int main()
{
    int i, j;
    int arr[] = {1, 2, 3};
    int m = sizeof(arr)/sizeof(arr[0]);
    printf("%d ", count(arr, m, 4));
    getchar();
    return 0;
}

```

It should be noted that the above function computes the same subproblems again and again. See the following recursion tree for $S = \{1, 2, 3\}$ and $n = 5$. The function $C(\{1\}, 3)$ is called two times. If we draw the complete tree, then we can see that there are many subproblems being called more than once.

$C() \rightarrow \text{count}()$

Since same subproblems are called again, this problem has Overlapping Subproblems property. So the Coin Change problem has both properties (see [this](#) and [this](#)) of a dynamic programming problem. Like other typical **Dynamic Programming(DP) problems**, recomputations of same subproblems can be avoided by constructing a temporary array table[][] in bottom up manner.

Dynamic Programming Solution

```
#include<stdio.h>
```

```
int count( int S[], int m, int n )
{
    int i, j, x, y;

    // We need n+1 rows as the table is constructed in bottom up manner
    // the base case 0 value case (n = 0)
    int table[n+1][m];

    // Fill the entries for 0 value case (n = 0)
    for (i=0; i<m; i++)
        table[0][i] = 1;

    // Fill rest of the table entries in bottom up manner
    for (i = 1; i < n+1; i++)
    {
        for (j = 0; j < m; j++)
        {
            // Count of solutions including S[j]
            x = (i-S[j] >= 0)? table[i - S[j]][j]: 0;

            // Count of solutions excluding S[j]
            y = (j >= 1)? table[i][j-1]: 0;

            // total count
            table[i][j] = x + y;
        }
    }
    return table[n][m-1];
}
```

```
// Driver program to test above function
```

```
int main()
{
    int arr[] = {1, 2, 3};
    int m = sizeof(arr)/sizeof(arr[0]);
    int n = 4;
```

```
printf(" %d ", count(arr, m, n));  
return 0;  
}
```

Time Complexity: $O(mn)$

Following is a simplified version of method 2. The auxiliary space required here is $O(n)$ only.

```
int count( int S[], int m, int n )  
{  
    // table[i] will be storing the number of solutions  
    // value i. We need n+1 rows as the table is constructed  
    // in bottom up manner using the base case (n = 0)  
    int table[n+1];  
  
    // Initialize all table values as 0  
    memset(table, 0, sizeof(table));  
  
    // Base case (If given value is 0)  
    table[0] = 1;  
  
    // Pick all coins one by one and update the table[] values  
    // after the index greater than or equal to the value of  
    // picked coin  
    for(int i=0; i<m; i++)  
        for(int j=S[i]; j<=n; j++)  
            table[j] += table[j-S[i]];  
  
    return table[n];  
}
```
