Simon's problem

From Wikipedia, the free encyclopedia
(Redirected from [Simon's algorithm](#))

In [computational complexity theory](#) and [quantum computing](#), **Simon's problem** is a computational problem in the model of [decision tree complexity](#) or query complexity, conceived by Daniel Simon in 1994.^[1] Simon exhibited a [quantum algorithm](#), usually called **Simon's algorithm**, that solves the problem exponentially faster than any (deterministic or [probabilistic](#)) classical algorithm.

Simon's algorithm uses $O(n)$ queries to the black box, whereas the best classical probabilistic algorithm necessarily needs at least $\Omega(2^{n/2})$ queries. It is also known that Simon's algorithm is optimal in the sense that any quantum algorithm to solve this problem requires $\Omega(n)$ queries.^{[2][3]} This problem yields an oracle separation between [BPP](#) and [BQP](#), unlike the separation provided by the [Deutsch-Jozsa algorithm](#), which separates [P](#) and [EQP](#).

Although the problem itself is of little practical value it is interesting because it provides an exponential speedup over any classical algorithm^[citation needed]. Moreover, it was also the inspiration for [Shor's algorithm](#). Both problems are special cases of the abelian [hidden subgroup problem](#), which is now known to have efficient quantum algorithms.

Problem description and algorithm [\[edit \]](#)

The input to the problem is a function (implemented by a black box) $f : \{0, 1\}^n \rightarrow \{0, 1\}^n$, promised to satisfy the property that for some $s \in \{0, 1\}^n$ we have for all $y, z \in \{0, 1\}^n$, $f(y) = f(z)$ if and only if $y = z$ or $y \oplus z = s$. Note that the case of $s = 0^n$ is allowed, and corresponds to f being a permutation. The problem then is to find s .

The set of n -bit strings is a \mathbb{Z}_2 vector space under bitwise [XOR](#). Given the promise, the preimage of f is either empty, or forms [cosets](#) with $n-1$ dimensions. Using quantum algorithms, we can, with arbitrarily high probability determine the basis vectors spanning this $n-1$ subspace since s is a vector orthogonal to all of the basis vectors.

Consider the [Hilbert space](#) consisting of the tensor product of the Hilbert space of input strings, and output strings. Using [Hadamard operations](#), we can prepare the initial state

$$\sum_x |x\rangle |0\rangle$$

and then call the oracle to transform this state to

$$\sum_x |x\rangle |f(x)\rangle$$

Hadamard transforms convert this state to

$$\sum_y \sum_x (-1)^{x \cdot y} |y\rangle |f(x)\rangle$$

We perform a simultaneous measurement of both registers. If $s \cdot y = 1$, we have [destructive interference](#). So, only the subspace $s \cdot y = 0$ is picked out. Given enough samples of y , we can figure out the $n-1$ basis vectors, and compute s .
