Radon transform

From Wikipedia, the free encyclopedia

In **mathematics**, the **Radon transform** in two dimensions, named after the Austrian mathematician **Johann Radon**, is the **integral transform** consisting of the integral of a function over straight lines. The transform was introduced in 1917 by Radon,^[1] who also provided a formula for the inverse transform. Radon further included formulas for the transform in three-dimensions, in which the integral is taken over planes. It was later generalised to higher-dimensional **Euclidean spaces**, and more broadly in the context of **integral geometry**. The **complex** analog of the Radon transform is known as the **Penrose transform**.

The Radon transform is widely applicable to **tomography**, the creation of an image from the projection data associated with cross-sectional scans of an object. If a function *f* represents an unknown density, then the Radon transform represents the projection data obtained as the output of a tomographic scan. Hence the inverse of the Radon transform can be used to reconstruct the original density from the projection data, and thus it forms the mathematical underpinning for **tomographic reconstruction**, also known as **image reconstruction**. The Radon transform data is often called a **sinogram** because the Radon transform of a **Dirac delta function** is a **distribution** supported on the graph of a sine wave. Consequently the Radon transform of a number of small objects appears graphically as a number of blurred sine waves with different amplitudes and phases. The Radon transform is useful in **computed axial tomography** (CAT scan), **barcode** scanners, **electron microscopy** of **macromolecular assemblies** like viruses and protein complexes, **reflection seismology** and in the solution of hyperbolic **partial differential equations**.

Definition [\[edit\]](#)

Let *f*(**x**) = *f*(*x*,*y*) be a compactly supported **continuous function** on **R**². The Radon transform, *Rf*, is a function defined on the space of straight lines *L* in **R**² by the **line integral** along each such line:

$$Rf(L) = \int_L f(\mathbf{x}) |d\mathbf{x}|.$$

Concretely, the parametrization of any straight line *L* with respect to arc length *z* can always be written

Radon transform.

Radon transform of the **indicator function** of two squares shown in the image below. Lighter regions indicate larger function values. Black indicates zero.

Original function is equal to one on the white region and zero on the dark region.

Shepp Logan phantom

Radon Inverse Radon transform transform

$$(x(z), y(z)) = ((z \sin \alpha + s \cos \alpha), (-z \cos \alpha + s \sin \alpha))$$

where s is the distance of L from the origin and α is the angle the normal vector to L makes with the x axis. It follows that the quantities (α, s) can be considered as coordinates on the space of all lines in \mathbf{R}^2 , and the Radon transform can be expressed in these coordinates by

$$\begin{aligned} Rf(\alpha, s) &= \int_{-\infty}^{\infty} f(x(z), y(z)) dz \\ &= \int_{-\infty}^{\infty} f((z \sin \alpha + s \cos \alpha), (-z \cos \alpha + s \sin \alpha)) dz \end{aligned}$$

More generally, in the n -dimensional [Euclidean space](#) \mathbf{R}^n , the Radon transform of a [compactly supported](#) continuous function f is a function Rf on the space Σ_n of all [hyperplanes](#) in \mathbf{R}^n . It is defined by

$$Rf(\xi) = \int_{\xi} f(\mathbf{x}) d\sigma(\mathbf{x})$$

for $\xi \in \Sigma_n$, where the integral is taken with respect to the natural hypersurface [measure](#), $d\sigma$ (generalizing the $|d\mathbf{x}|$ term from the 2-dimensional case). Observe that any element of Σ_n is characterized as the solution locus of an equation

$$\mathbf{x} \cdot \alpha = s$$

where $\alpha \in S^{n-1}$ is a [unit vector](#) and $s \in \mathbf{R}$. Thus the n -dimensional Radon transform may be rewritten as a function on $S^{n-1} \times \mathbf{R}$ via

$$Rf(\alpha, s) = \int_{\mathbf{x} \cdot \alpha = s} f(\mathbf{x}) d\sigma(\mathbf{x}).$$

It is also possible to generalize the Radon transform still further by integrating instead over k -dimensional affine subspaces of \mathbf{R}^n . The [X-ray transform](#) is the most widely used special case of this construction, and is obtained by integrating over straight lines.

Generalized Radon Transform [\[edit\]](#)

Let $s \in \mathbf{R}$, $\phi \in [0, 2\pi]$. We let $\mu(\phi, x)$ be a smooth function, 2π periodic in ϕ defined on $\mathbf{R} \times \mathbf{R}^2$. Then, the generalized radon transform is defined as follows.

$$R_{\mu}f(\phi, s) = \int_{x \in L(\phi, s)} f(x) \mu(\phi, x) dx$$

Where dx is the arc length measure on the line $L(\phi, s)$. Note, that the transform integrates the weighted function $f(x)$ along the lines $L(\phi, s)$.

Relationship with the Fourier transform [\[edit\]](#)

Main article: [Projection-slice theorem](#)

The Radon transform is closely related to the [Fourier transform](#). For a function of one variable the Fourier transform is defined by

$$\hat{f}(\omega) = \int_{-\infty}^{\infty} f(x) e^{-2\pi i x \omega} dx.$$

and for a function of a 2-vector $\mathbf{x} = (x, y)$,

$$\hat{f}(\mathbf{w}) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(\mathbf{x}) e^{-2\pi i \mathbf{x} \cdot \mathbf{w}} dx dy.$$

For convenience define $R_{\alpha}[f](s) = R[f](\alpha, s)$ as it is only meaningful to take the Fourier transform in the s variable. The [Fourier slice theorem](#) then states

$$\widehat{R_{\alpha}[f]}(\sigma) = \hat{f}(\sigma \mathbf{n}(\alpha))$$

where

$$\mathbf{n}(\alpha) = (\cos \alpha, \sin \alpha).$$

Thus the two-dimensional Fourier transform of the initial function is the one variable Fourier transform of the Radon transform of that function. More generally, one has the result valid in n dimensions

$$\hat{f}(r\alpha) = \int_{-\infty}^{\infty} Rf(\alpha, s) e^{-2\pi i s r} ds.$$

Indeed, the result follows at once by computing the two variable Fourier integral along appropriate slices:

$$\hat{f}(r\alpha) = \int_{-\infty}^{\infty} ds \int_{\mathbf{x} \cdot \alpha = s} e^{-2\pi i r(\mathbf{x} \cdot \alpha)} dm(\mathbf{x}).$$

An application of the [Fourier inversion formula](#) also gives an explicit inversion formula for the Radon transform, and thus shows that it is invertible on suitably chosen spaces of functions. However this form is not particularly useful for numerical inversion, and faster discrete inversion methods exist.

Dual transform [\[edit\]](#)

The dual Radon transform is a kind of [adjoint](#) to the Radon transform. Beginning with a function g on the space Σ_n , the dual Radon transform is the function R^*g on \mathbf{R}^n defined by

$$R^*g(x) = \int_{x \in \xi} g(\xi) d\mu(\xi).$$

The integral here is taken over the set of all lines incident with the point $x \in \mathbf{R}^n$, and the measure $d\mu$ is the unique [probability measure](#) on the set $\{\xi | x \in \xi\}$ invariant under rotations about the point x .

Concretely, for the two-dimensional Radon transform, the dual transform is given by

$$R^*g(x) = \frac{1}{2\pi} \int_{\alpha=0}^{2\pi} g(\alpha, \mathbf{n}(\alpha) \cdot \mathbf{x}) d\alpha.$$

In the context of image processing, the dual transform is commonly called *backprojection*^[2] as it takes a function defined on each line in the plane and 'smears' or projects it back over the line to produce an image.

[Computationally efficient inversion formulas](#) reconstruct the image from the points where the back-projection lines meet.

Intertwining property [\[edit\]](#)

Let Δ denote the [Laplacian](#) on \mathbf{R}^n :

$$\Delta = \frac{\partial^2}{\partial x_1^2} + \cdots + \frac{\partial^2}{\partial x_n^2}.$$

This is a natural rotationally invariant second-order [differential operator](#). On Σ_n , the "radial" second derivative

$$Lf(\alpha, s) \equiv \frac{\partial^2}{\partial s^2} f(\alpha, s)$$

is also rotationally invariant. The Radon transform and its dual are [intertwining operators](#) for these two differential operators in the sense that^[3]

$$R(\Delta f) = L(Rf), \quad R^*(Lg) = \Delta(R^*g).$$

Inversion formulas [\[edit\]](#)

Explicit and computationally efficient inversion formulas for the Radon transform and its dual are available. The Radon transform in n dimensions can be inverted by the formula^[4]

$$c_n f = (-\Delta)^{(n-1)/2} R^* R f$$

where

$$c_n = (4\pi)^{(n-1)/2} \frac{\Gamma(n/2)}{\Gamma(1/2)}.$$

and the power of the Laplacian $(-\Delta)^{(n-1)/2}$ is defined as a [pseudodifferential operator](#) if necessary by the [Fourier transform](#)

$$\mathcal{F} [(-\Delta)^{(n-1)/2} \phi] (\xi) = |2\pi\xi|^{n-1} \mathcal{F}\phi(\xi).$$

For computational purposes, the power of the Laplacian is commuted with the dual transform R^* to give^[5]

$$c_n f = \begin{cases} R^* \frac{d^{n-1}}{ds^{n-1}} R f & n \text{ odd} \\ R^* H_s \frac{d^{n-1}}{ds^{n-1}} R f & n \text{ even} \end{cases}$$

where H_s is the [Hilbert transform](#) with respect to the s variable. In two dimensions, the operator $H_s d/ds$ appears

in image processing as a **ramp filter**.^[6] One can prove directly from the Fourier slice theorem and change of variables for integration that for a compactly supported continuous function f of two variables

$$f = \frac{1}{2} R^* H_s \frac{d}{ds} R f.$$

Thus in an image processing context the original image f can be recovered from the 'sinogram' data Rf by applying a ramp filter (in the s variable) and then back-projecting. As the filtering step can be performed efficiently (for example using **digital signal processing** techniques) and the back projection step is simply an accumulation of values in the pixels of the image, this results in a highly efficient, and hence widely used, algorithm.

Explicitly, the inversion formula obtained by the latter method is^[2]

$$f(x) = \frac{1}{2} (2\pi)^{1-n} (-1)^{(n-1)/2} \int_{S^{n-1}} \frac{\partial^{n-1}}{\partial s^{n-1}} Rf(\alpha, \alpha \cdot x) d\alpha$$

if n is odd, and

$$f(x) = (2\pi)^{-n} (-1)^{n/2} \int_{-\infty}^{\infty} \frac{1}{q} \int_{S^{n-1}} \frac{\partial^{n-1}}{\partial s^{n-1}} Rf(\alpha, \alpha \cdot x + q) d\alpha dq$$

if n is even.

The dual transform can also be inverted by an analogous formula:

$$c_n g = (-L)^{(n-1)/2} R(R^* g).$$
