

# Red-Black Tree | Set 1 (Introduction)

Red-Black Tree is a self-balancing Binary Search Tree (BST) where every node follows following rules.

1) Every node has a color either red or black.

2) Root of tree is always black.

3) There are no two adjacent red nodes (A red node cannot have a red parent or red child).

4) Every path from root to a NULL node has same number of black nodes.

## Why Red-Black Trees?

Most of the BST operations (e.g., search, max, min, insert, delete.. etc) take  $O(h)$  time where  $h$  is the height of the BST. The cost of these operations may become  $O(n)$  for a skewed Binary tree. If we make sure that height of the tree remains  $O(\log n)$  after every insertion and deletion, then we can guarantee an upper bound of  $O(\log n)$  for all these operations. The height of a Red Black tree is always  $O(\log n)$  where  $n$  is the number of nodes in the tree.

## Comparison with AVL Tree

The AVL trees are more balanced compared to Red Black Trees, but they may cause more rotations during insertion and deletion. So if your application involves many frequent insertions and deletions, then Red Black trees should be preferred. And if the insertions and deletions are less frequent and search is more frequent operation, then AVL tree should be preferred over Red Black Tree.

## How does a Red-Black Tree ensure balance?

A simple example to understand balancing is, a chain of 3 nodes is not possible in red black tree. We can try any combination of colors and see all of them violate Red-Black tree property.

A chain of 3 nodes is not possible in Red-Black Trees. Following are **NOT** Red-Black Trees

Following are different possible Red-Black Trees with above 3 keys

From the above examples, we get some idea how Red-Black trees ensure balance. Following is an important fact about balancing in Red-Black Trees.

**Every Red Black Tree with  $n$  nodes has height  $\leq 2\log_2(n+1)$**

This can be proved using following facts:

- 1) For a general Binary Tree, let  $k$  be the minimum number of nodes on all root to NULL paths, then  $n \geq 2^k - 1$  (Ex. If  $k$  is 3, then  $n$  is atleast 7). This expression can also be written as  $k \leq 2\log_2(n+1)$
- 2) From property 4 of Red-Black trees and above claim, we can say in a Red-Black Tree with  $n$  nodes, there is a root to leaf path with at-most  $\log_2(n+1)$  black nodes.
- 3) From property 3 of Red-Black trees, we can claim that the number black nodes in a Red-Black tree is at least  $\lfloor n/2 \rfloor$  where  $n$  is total number of nodes.

From above 2 points, we can conclude the fact that Red Black Tree with  $n$  nodes has height  $\leq 2\log_2(n+1)$

In this post, we introduced Red-Black trees and discussed how balance is ensured. The hard part is to maintain balance when keys are added and removed. We will soon be discussing insertion and deletion operations in coming posts on Red-Black tree.

### Exercise:

- 1) Is it possible to have all black nodes in a Red-Black tree?
- 2) Draw a Red-Black Tree that is not an **AVL tree** structure wise?
